Outcomes of Participants in Cornell Cooperative Extension Parent Education Programs, 2021-2022

By Julia Chapman & Kimberly Kopko

The Cornell Cooperative Extension (CCE) system offers a variety of programs for parents and caregivers. Offered at CCE associations throughout New York, these programs reach a wide range of families and seek to promote positive parenting and, ultimately, healthy family and child development. This report presents data collected from participants in CCE parent education programs between July 2021 and September 2022. Participants included parents and caregivers taking part in programs that comprised at least six hours of content delivery. Data were collected from participants at the first session (a pre-test) and at the last session (a post-test). Results of the analysis of these data are shown below.

Demographics of Participants in CCE Parent Education Programs

A total of six parent education programs were evaluated, as shown below. The largest number of participants took part in the Home Visitation Program (40%) and the PS It Works! Program (23%).

Outcomes at a Glance

In 2021-2022, 288 participants attended CCE parenting programs across New York State. Participants took part in one of six parenting programs in seven counties across the state.

The majority of participants in the parenting education classes were:

- Female (69%)
- White (70%)
- Single (43%)

A total of 168 participants attended their final class and 7 out of 10 items on the survey showed significant improvements between the pre- and post-test.
The following summaries use data from 288 participants who completed a pre-test survey given at the first session of their parent education class. In total, data was collected from seven counties throughout the state. Albany County had the largest share of participants (23%) followed by Tompkins County (20%) and Lewis County (18%).
The majority (69%) of participants in parent education classes were female. The highest level of educational attainment reached among the participants varied widely, with the greatest number of participants reaching 12th grade or a GED (35%) followed by those having completed between 9th and 11th grade (15%), and those having attended, but not graduated from college (13%). The majority of the participants in parent education classes were white (70%), and 43% of the participants were single.
Race:
- White: 70%
- African American or Black: 9%
- Refused to Respond: 8%
- Hispanic: 6%
- Asian: 3%
- Other: 1%
- American Indian: 3%

Marital Status:
- Single: 43%
- Married/Partnered: 39%
- Divorced: 8%
- Separated/Widowed: 8%
- Refused to answer: 1%
Pre-Post Survey Results

This study used a pre- and post-test evaluation, in which the participants were asked to answer two identical surveys—one given at the first session of the class and another given after the completion of the last parenting class. The survey included ten questions about parenting attitudes, behaviors, and knowledge. The pre/post study design allows researchers to see if participants’ attitudes, behaviors, and knowledge change during the course of the parenting programs. Using this type of research design does not allow one to determine whether taking part in the parent education class caused a change in knowledge, attitude or behaviors; such changes could occur for other reasons outside of the program. However, it is possible that any significant pre-to-post changes in parenting attitudes, behaviors and knowledge that are observed may have resulted from taking part in the program.

The following evaluation is based on information provided by 168 participants, who completed a parent education program and completed both a pre- and a post-test survey. Seven out of ten items on the survey showed significant improvements from the pre- to the post-test. Specifically, CCE parent education participants reported increased: belief in their skills to be a good caregiver, confidence in explaining the reasons for rules, patience with their child, confidence in making rules that take their child’s needs into consideration, frequency in telling another adult something positive about their child, feelings of having enough support from others, and decreased frequency in yelling at their child.

A p-value generated from a paired t-test was used as a statistical measure to determine whether a change in a given survey question between the pre- and post-test was significant. A p-value of .10 or less was considered statistically significant. This means that we can say with 90% certainty that the pre-to-post changes in participant responses are not due to chance.

In comparing participants' pre- and post-test survey results, the following three questions showed statistically significant changes at the 1% level.
I honestly believe I have the skills necessary to be a good caregiver.

Pre: 3.96
Post: 4.27

I try to explain the reasons for the rules I make.

Pre: 3.26
Post: 3.55
In comparing participants’ pre- and post-test survey results, the following three questions showed statistically significant changes at the 5% level.
In comparing participants’ pre- and post-test survey results, the following question showed statistically significant changes at the 10% level.
These results indicate that seven out of ten measures of parenting attitudes, behaviors and knowledge improved significantly from the pre- to the post-test. This suggests that, across the state, CCE parent education programs may have had a positive impact on their participants.
